Michael MacWilliams, Anchor QEA

Notes

- I conducted this work while working at USGS with David Schoellhamer, Paul Work, and others
- I no longer represent the USGS
- The content in these slides is from material approved for public release
- Further information can be found in our 2021 paper:

Downing-Kunz, M.A., Work, P.A. & Schoellhamer, D.H. Tidal Asymmetry in Ocean-Boundary Flux and In-Estuary Trapping of Suspended Sediment Following Watershed Storms: San Francisco

Estuary, California, USA. Estuaries and Coasts (2021).

https://doi.org/10.1007/s12237-021-00937-y

Background

- Watershed and sediment discharge enter SF Bay from Sacramento and San Joaquin Rivers, and smaller local tributaries
- Sediment supply to SF Bay has changed over time
- One motivation for this work was to improve understanding of the SF Bay sediment budget
- Quantifying the SF Bay sediment budget aids in management of:
 - Navigation dredging
 - Contaminant transport
 - Shoreline resilience
 - Wetland restoration
 - Beach erosion
 - Aggregate mining

Sediment fluxes and budgets

van Rijn 2006

Flux: rate of transport at a cross-section

Flux = discharge * concentration

Budget: a way to account for sediment gains and losses within a region of interest

Change in storage = inflow - outflow

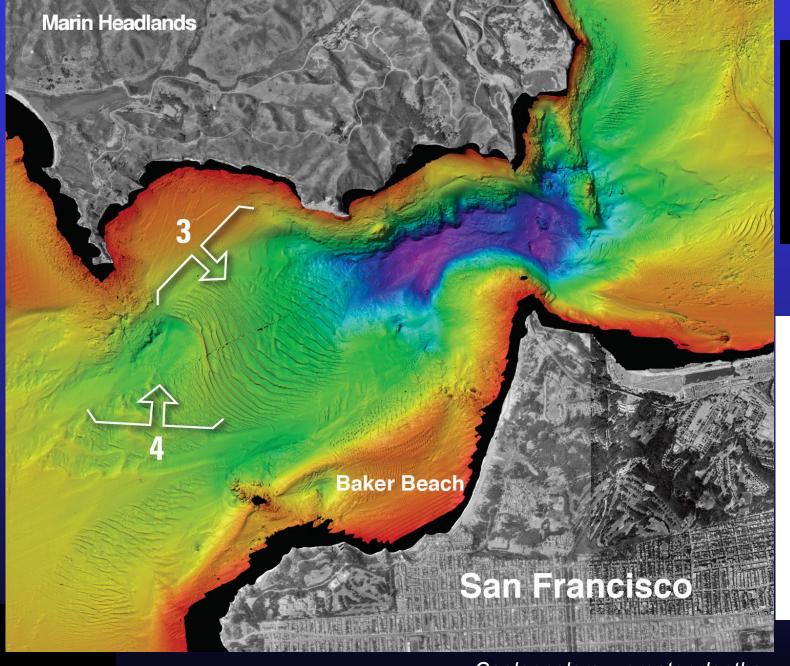

Suspended-sediment flux at Golden Gate

- Sediment budgets show that suspended-sediment flux at the Golden Gate is the largest and most uncertain term
- Objective: Collect sediment flux measurements during high runoff, build upon existing work documented in Erikson et al. (2013)

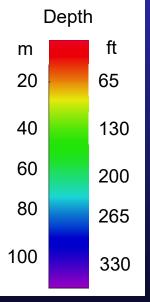

Source	Years	Method	Sediment outflow (Mt/yr)	
Gilbert (1917)	1849-1914	Arbitrary estimate	20.2	
Ogden/Beeman/Krone (1992)	1955-1990	Mass conservation	1.3	
Schoellhamer et al. (2005)	1955-1990	Mass conservation	5.0	
Schoellhamer et al. (2005)	1995-2002	Mass conservation	4.2	
Erikson et al. (2013)	2004-2011	Surrogate flux	5.0	

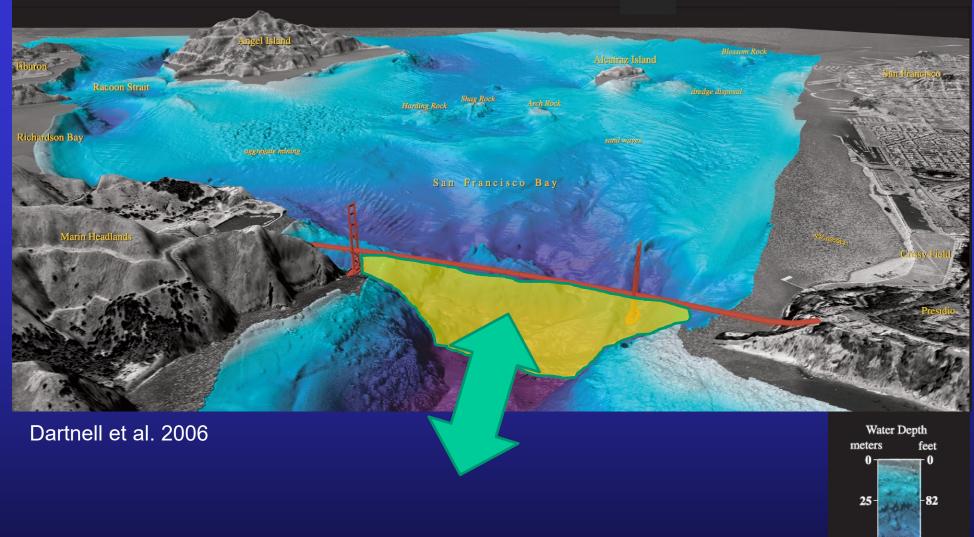

Golden Gate is extreme—great depths, fast currents

- 6 ft (1.8 m) tidal range
- ~25% of SF Bay volume exchanged per tide

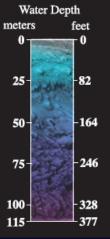

Cooler colors = greater depths

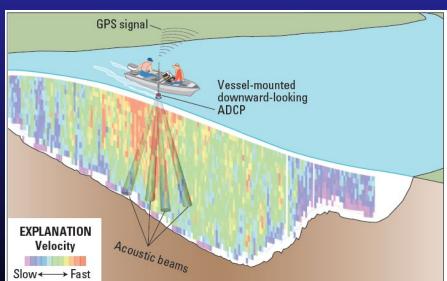

Sediment flux = discharge * concentration

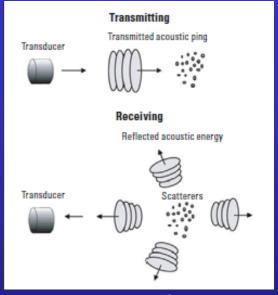

Acoustic Doppler Current Profiler (ADCP): The sediment flux whisperer

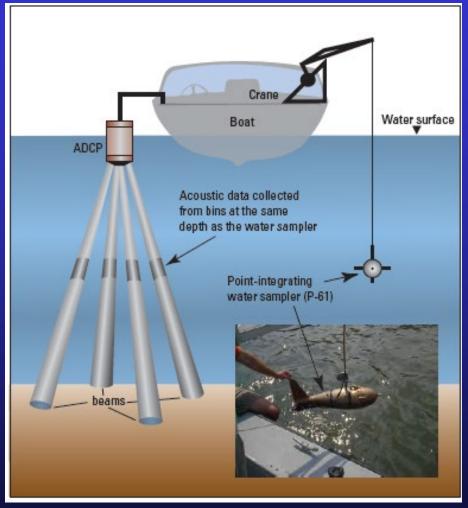

Simpson 2001

Discharge = velocity * area

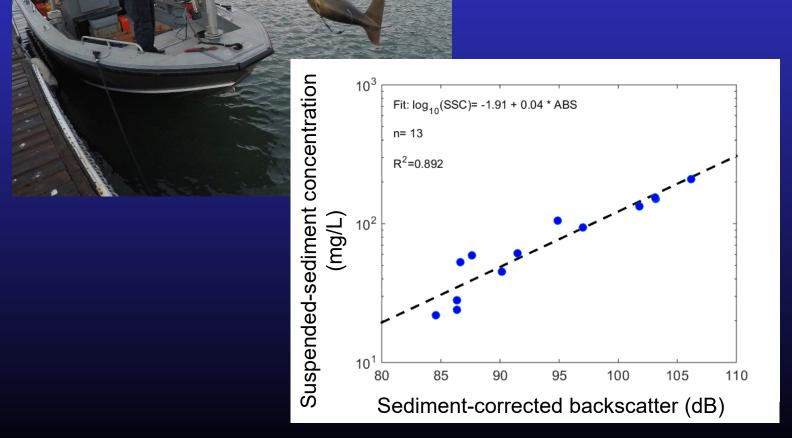

Sediment flux = discharge * concentration

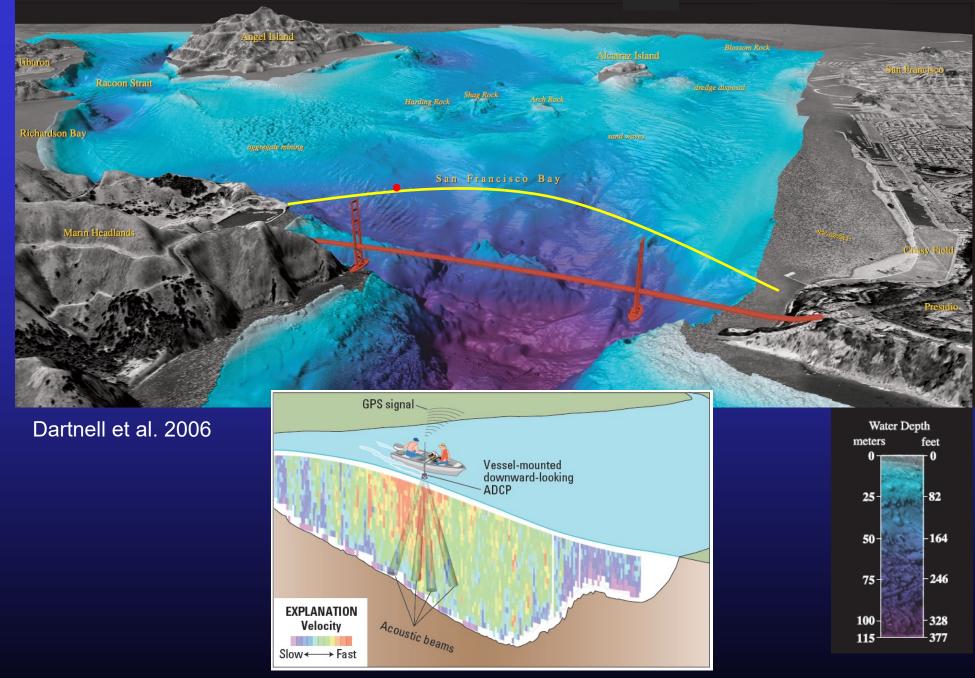

Calibration of backscatter to suspended-sediment concentration (SSC)

Mueller et al. 2013

Underway aboard R/V Questuary on a calm day

Fairweather sediment sampling

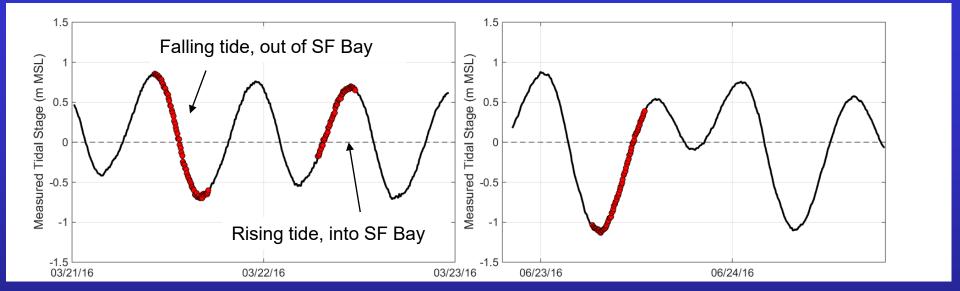

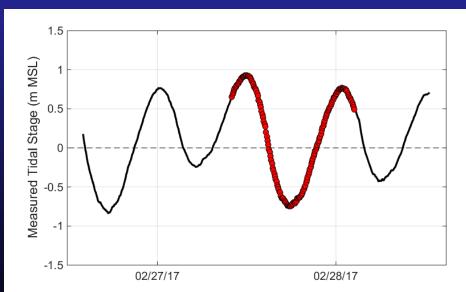

Views from the stormy day

ADCP transects by field campaign

March 2016, *n* = 18

June 2016, n = 7

High spatial resolution but

Low temporal resolution

February 2017, n = 32

Results

	Peak water flux (1x10 ⁵ m ³ /s)		Peak sediment flux (1x10 ⁵ kg/min)		Peak transect- average SSC (mg/L)	
Field Date	Ebb	Flood	Ebb	Flood	Ebb	Flood
Mar 2016	1.3	1.0	1.6	< 2.0	25	< 33
Jun 2016	1.1	0.9	1.2	< 1.3	21	< 35
Feb 2017	1.3	1.1	3.0	< 4.6	62	< 68

Downing-Kunz et al., 2021

- Peak water flux on ebb
- Peak sediment flux on flood
- Peak cross-sectional average SSC on flood

Challenges

- Getting the timing right
 - Physical factors are complex
 - Scheduling an appropriate vessel
- Labor intensive
 - Low temporal resolution
- ADCP frequency
 - Trade-off between range and sensitivity

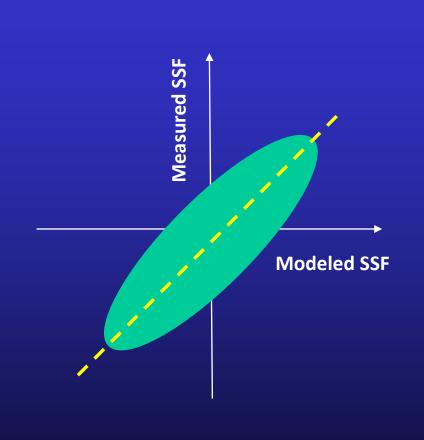

Next step: Modeling suspended-sediment flux (SSF)

Sediment Flux through the Golden Gate

Presented by

Maureen Downing-Kunz, PhD

Michael MacWilliams, PhD, PE

Focus of the Modeling Study

Goal

 Evaluate modeled sediment flux through the Golden Gate and compare to USGS data-based estimate of sediment flux

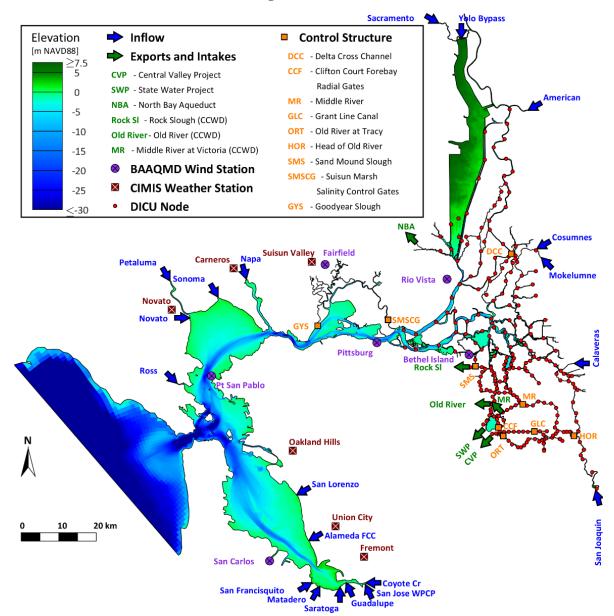

Approach

- Simulate hydrodynamics, waves, and sediment transport throughout the Bay-Delta
- Validate predicted SSC
- Compare USGS estimated sediment flux to modeled sediment flux and evaluate predicted sediment flux over a 4.5-month simulation period

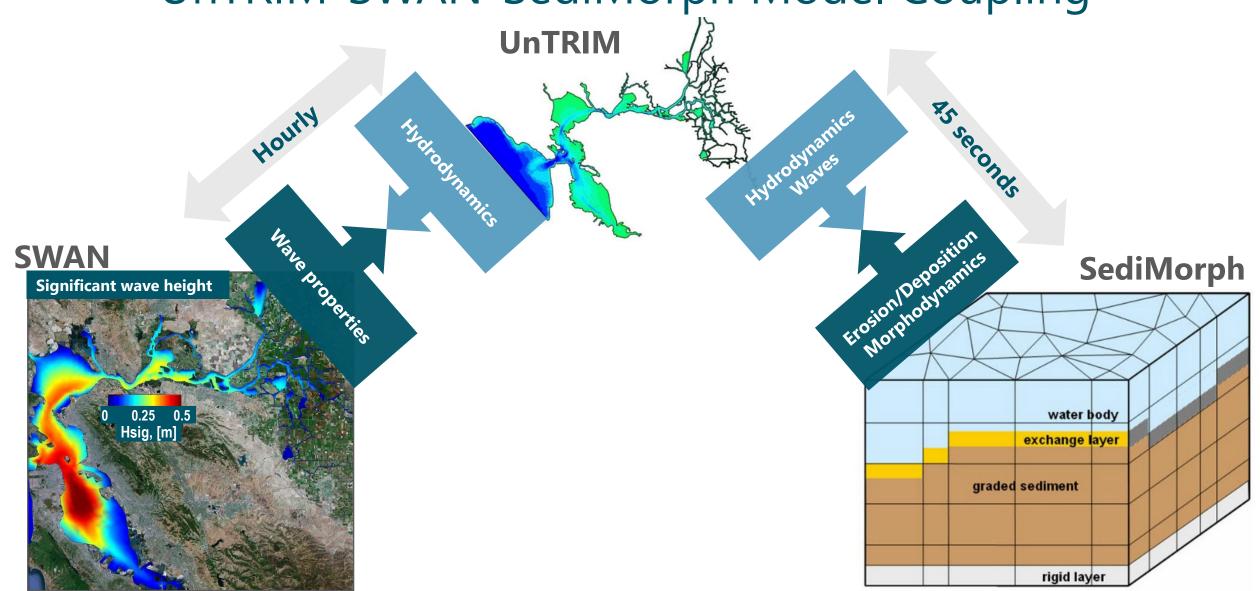

Hydrodynamic Modeling

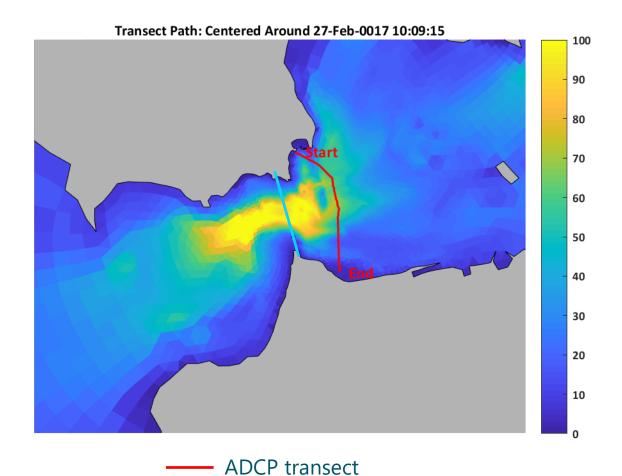

UnTRIM Bay-Delta Model

UnTRIM-SWAN-SediMorph Model Coupling

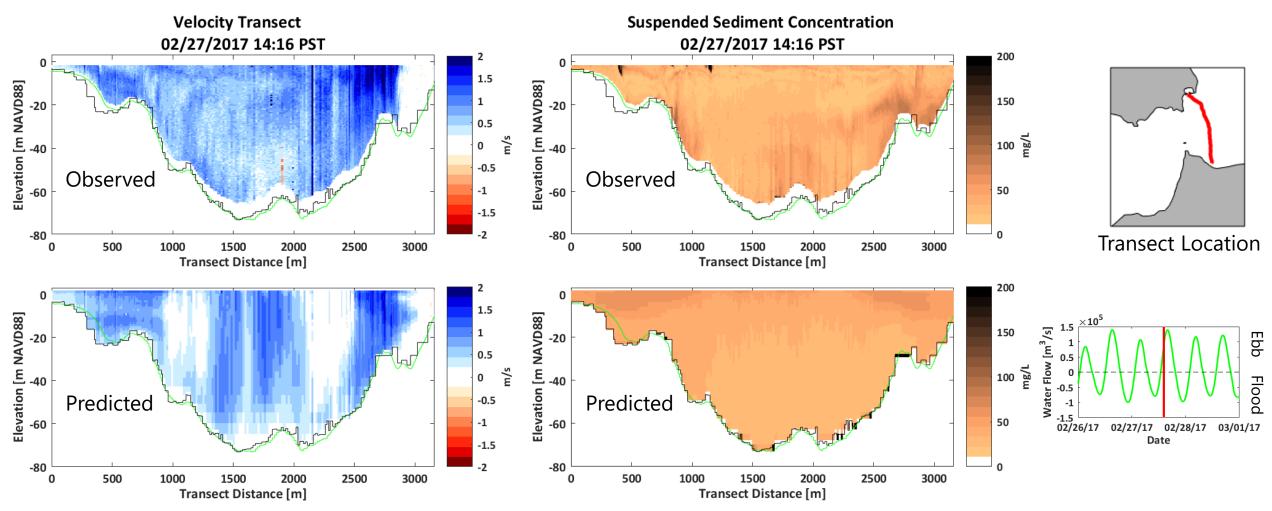

Sediment Flux Calculation

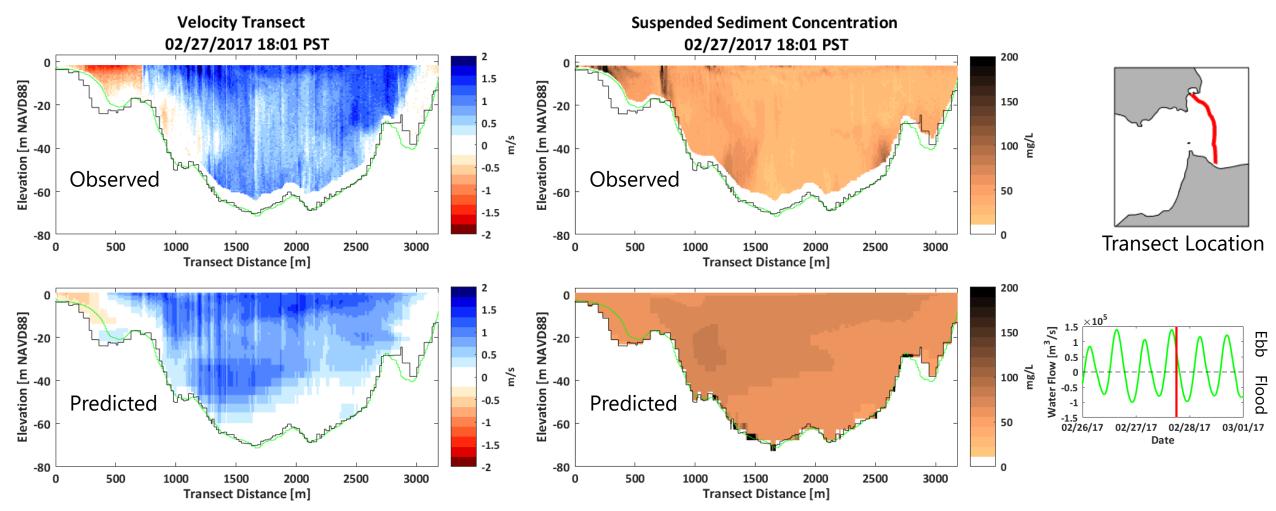

Modeled cross section

ADCP Transects: Increasing Ebb Flow

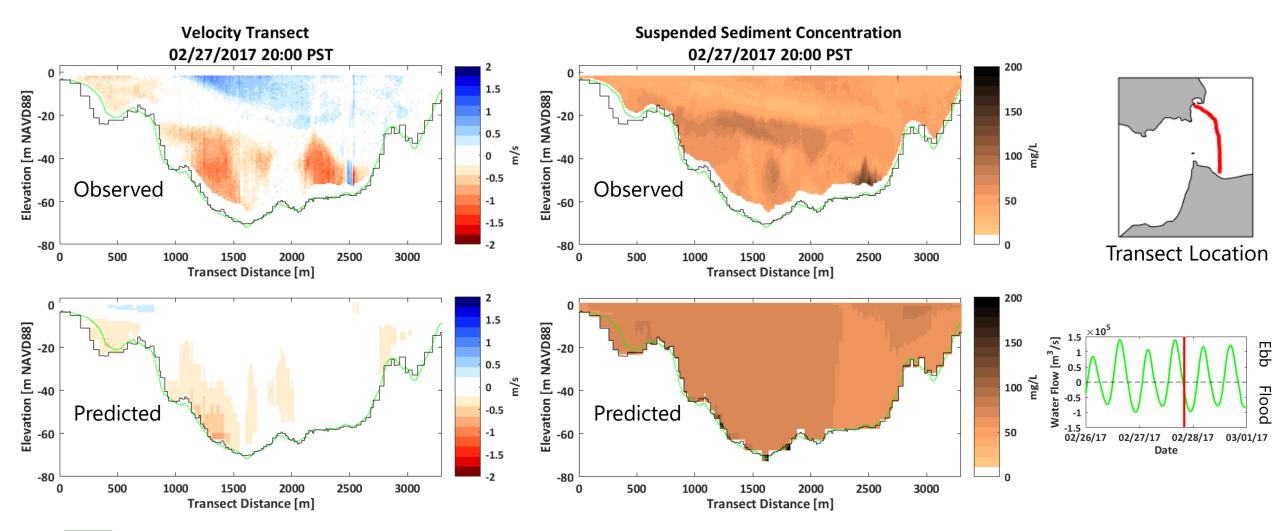

ADCP Transects: Decreasing Ebb Flow

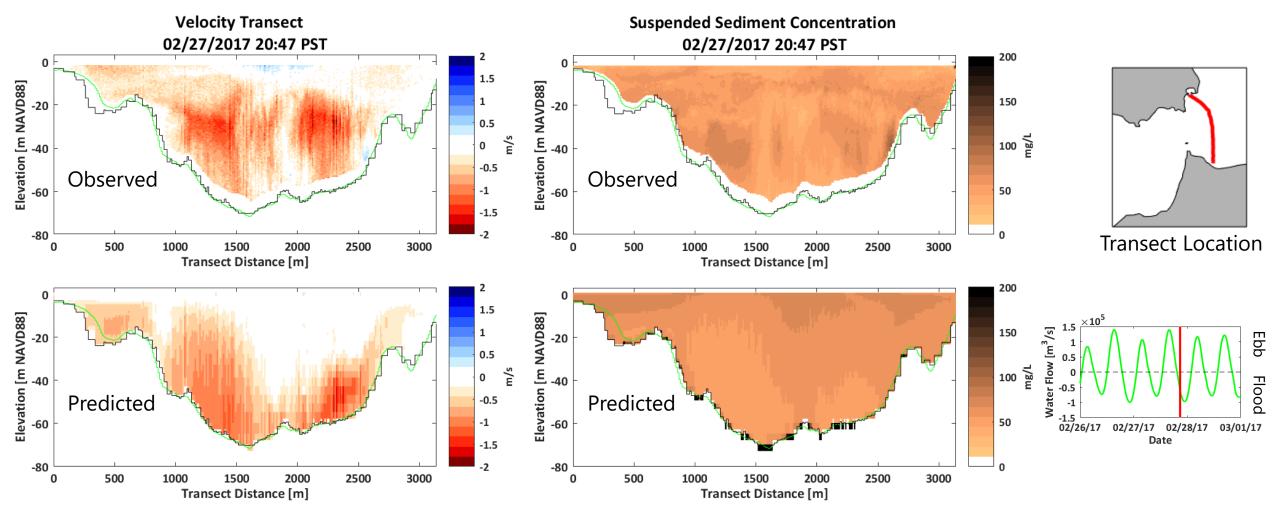

ADCP Transects: Near Slack Before Flood

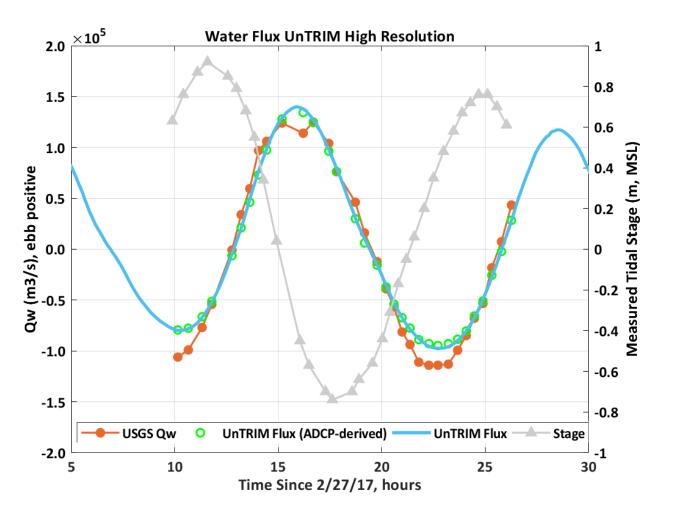

ADCP Transects: Increasing Flood Flow

Water Flux Through the Golden Gate

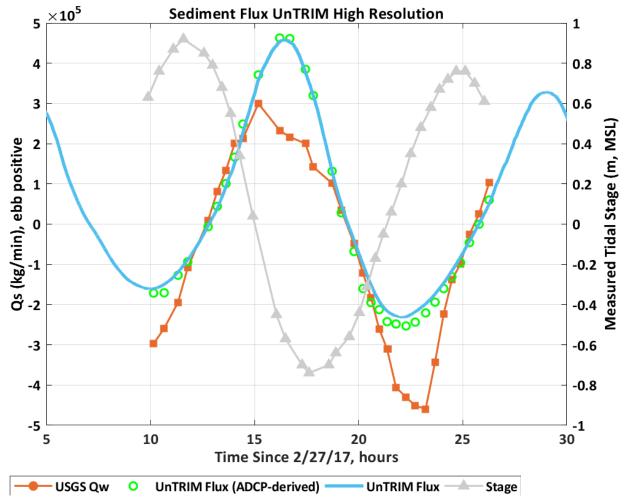

- Measurements and predictions of water flux for 32 transects over 16.5 hours
- Compared to continuous model-predicted water flux at Golden Gate (blue)
- Model predicts slightly larger (+5%) ebb flow and smaller (-13%) flood flow

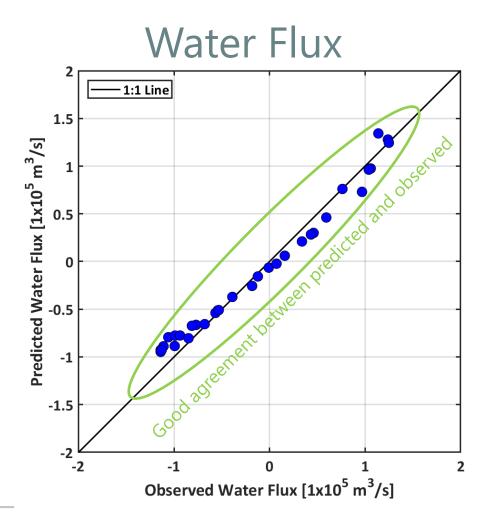

Sediment Flux Through the Golden Gate

- Measurements and predictions of sediment flux for 32 transects over 16.5 hours
- Compared to continuous model-predicted sediment flux at Golden Gate (blue)
- Model predicts larger ebb sediment flux and smaller flood sediment flux than measured

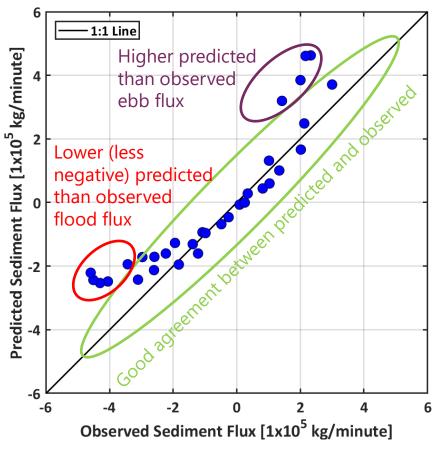

Water and Sediment Flux Through the Golden Gate

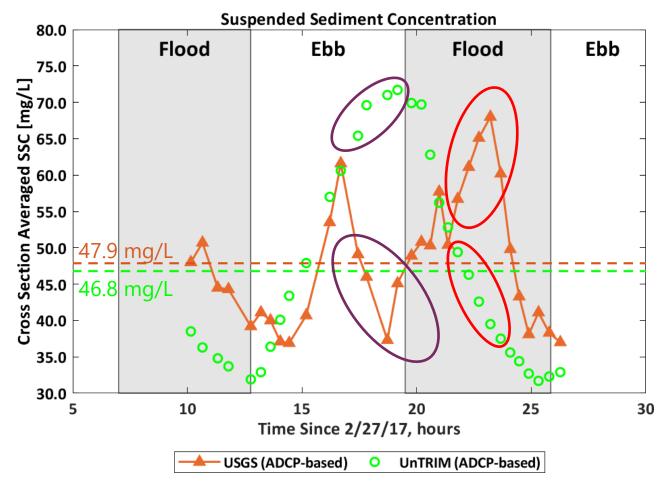

Sediment Flux

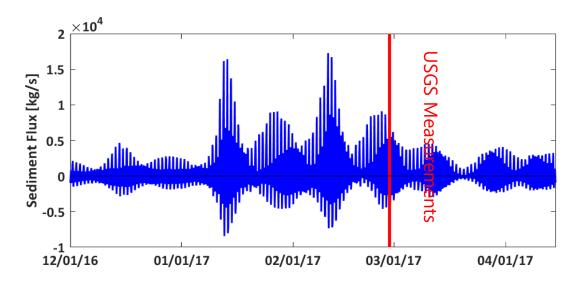

Sediment Flux Through the Golden Gate

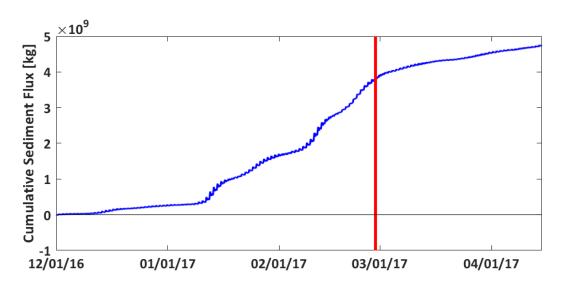

- Sediment flux equals flow times concentration
- Model predicts similar average concentration (46.8 mg/L) to measurements (47.9 mg/L) over 32 transects
- Largest difference between modeled and measured sediment flux results from different pattern in average SSC over the tidal cycle

Predicted Sediment Flux at Golden Gate

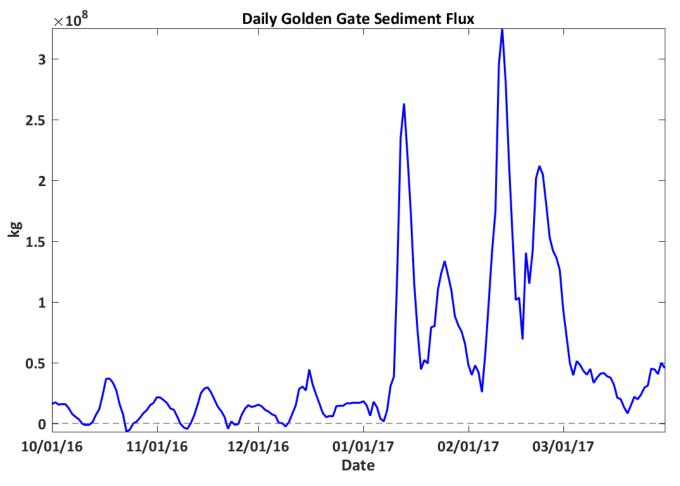

- Model provides estimate of sediment flux over longer timescales
- USGS measurements provide estimate over partial day (16.5 hours)
- Observations necessary to validate model
- Uncertainty in both observations and model

Predicted Daily Sediment Flux at Golden Gate

- Overall goal is to improve estimates of sediment flux at Golden Gate over longer timescales
- Combination of field data collection and modeling can improve our understanding of sediment flux
 - Long-term sediment flux estimates are essential for sediment budgets
